

Streamlining IT Procurement: Automating Standard Laptop Orders

4. Scalability & Future Plan

Date: 30.09.2026

Team ID: MKU201 Laptop Orders

The current solution automates one standard laptop procurement scenario. The architecture can be extended to support additional devices, rules, approvals, and fulfillment teams without changing the basic Service Catalog-to-Flow Designer approach.

Current Scope

The current implementation focuses on the Standard Laptop catalog item and automatically creates a Catalog Task for an approved request, assigning the task to Hardware.

Scalability Opportunities

- Add additional catalog items such as desktops, monitors, keyboards, and other IT equipment.
- Use decision logic to route different equipment types to different assignment groups.
- Support multiple laptop configurations based on user role, department, or location.
- Create multiple fulfillment tasks when a request contains several items.
- Introduce reusable subflows for common procurement activities.
- Add notifications to users and fulfillment teams when task states change.

Future Automation Enhancements

- Integrate inventory or asset-management information to check availability before fulfillment.
- Add automated approval rules based on cost, department, or request type.
- Create escalation rules for overdue procurement tasks.
- Capture fulfillment metrics such as processing time and task completion time.
- Integrate with procurement or vendor systems where appropriate.

Maintainability

Keeping the flow modular and using Service Catalog variables, decision logic, and reusable actions can make future changes easier. Documentation and screenshots should be updated whenever the workflow is expanded.

Future Success Measures

- Reduced manual task creation.
- Faster routing to the correct fulfillment group.
- Fewer manual assignment errors.
- Better visibility of request and task status.
- Ability to support more IT procurement categories through the same automation pattern.

Supporting Evidence
